

Abstract

A method of creating a logical device performing polynomial division includes using a hardware description language to build code directly describing synthesizable logic for performing the polynomial division. The logic is then implemented on a target device. The code receives as inputs a parameter identifying a polynomial and a parameter identifying a number of data bits for which the polynomial division is performed. For a given n -degree polynomial, performing the polynomial division includes calculating a next n -term remainder for a data unit having d terms.
